

Unions in C

By: Yehia M. Abu Eita

Outlines

- Introduction
- Creating new union type
- Declaring a union variable
- Union variables in memory
- Accessing a union variable members

Introduction

- Union is a **non-primitive** data type that stores **different types of data**.
- Unions are used to **group different types of data together with a momentarily time access / shared memory**.
- You have to **create** the **new union** type **first**, and **then** you can **declare** union variables.
- Union **size differs** according to the **largest member size**.
- Using unions will **reduce memory** usage.

Creating new union type

- A creation of the new union data type must occur first, **written first in the .c file**, before any declaration occurs.
- **Creation** of a data type **doesn't mean** that we **allocate** anything from the **memory**.
- **Creation is just informing the compiler.**

```
union student
{
    unsigned char name[16];
    unsigned int id;
};
```

Declaring a union variable

- After creating a new union data type, you can declare a variable.
- Declaration Example:
 - `union student x;`
- Also you can set **only one initial value** for **either union** variable **members**.
- Definition Example:
 - `union student x = {"Ahmed"};`

Union variables in memory

16 Bytes

- Defining a union variable:
 - `union student x = {"Ahmed"};`
- The size of this variable into the memory is **16 bytes**.
 - **16 bytes for the array of characters "name" because it is the largest member.**

```
union student
{
    unsigned char name[16];
    unsigned int id;
};
```

0	'A'
1	'h'
2	'm'
3	'e'
4	'd'
5	'\0'
6	'\0'
7	'\0'
8	'\0'
9	'\0'
10	'\0'
11	'\0'
12	'\0'
13	'\0'
14	'\0'
15	'\0'
16	
17	
18	
19	
20	

Accessing a union variable members

- Use the **'.'** **operator** to access the union members.
- Access union members is for reading and writing.
- Examples:

```
- union student x = {"Ahmed"};  
- x.name[1] = 'H';  
- x.id = 1000;    // 0x03E8
```

```
union student  
{  
    unsigned char name[16];  
    unsigned int id;  
};
```

0	x.id = 0xE8
1	x.id = 0x03
2	x.name[2] = 'm'
3	x.name[3] = 'e'
4	x.name[4] = 'd'
5	x.name[5] = '\0'
6	x.name[6] = '\0'
7	x.name[7] = '\0'
8	x.name[8] = '\0'
9	x.name[9] = '\0'
10	x.name[10] = '\0'
11	x.name[11] = '\0'
12	x.name[12] = '\0'
13	x.name[13] = '\0'
14	x.name[14] = '\0'
15	x.name[15] = '\0'
16	
17	
18	
19	
20	

Summary

- Now you are familiar with unions in C.
- You can create, declare and manipulate unions.
- You have learned that union size depends the largest member size
- Accessing union using the ' .' operator.
- Remember that only one initial value is given to a union member.
- You must control reading and writing to the union variables in order not to lose data.
